PART 1 FEEDBACK REPORT ANALYSIS.

EcoCycle Solutions – Part 2 Changelog

This changelog outlines everything which includes corrections and improvements made to the EcoCycle Solutions website after receiving Part 1 feedback from the lecturer Mr. Dlamini. The website was redesigned and enhanced to meet the requirements for Part 2 of the project.

Part 1 Feedback

Corrections Implemented in Part 2

Website looked very basic, so I improved the website to look professional, eco-themed colour scheme, modern typography, improved spacing and better page structure. No external stylesheet was included so I created and linked an external CSS file (style.css) to all HTML pages for consistent styling across the website. A weak navigation structure so I improved the navigation bar with better alignment, responsive behaviour and a sticky navigation layout so it could look more advanced. Limited responsiveness, which was not good for the website engagement, so what I did was that I implemented responsive design using CSS Grid, Flexbox and media queries to ensure compatibility across mobile, tablet and desktop devices this in fact did increase more engagement. Another disadvantage was poor layout structure this was not effective to my website, so I decided to redesigned sections using card layouts, improved spacing and I organised content hierarchy. Informal website presentation which did appeal well to my customers and that would have made a loss in my business so what I did was updated text content using formal and professional language which could overall grab the attention of the customer. Unclear booking/contact functionality on the website was one of the disadvantage factors I had to endure so I added a structured contact and booking form where users can submit workshop or service requests using fields such as name, email, and service selection.

Responsive Design Improvements:

I Implemented a responsive web design using media queries to ensure compatibility within and across desktop, tablet and mobile devices. CSS Grid and Flexbox layouts were used to create flexible page structures that automatically adjust to different screen sizes. The navigation menus, text, spacing and content sections were used for smaller screens to improve accessibility and usability and basically enhance the website. Images were implemented using percentage widths and object-fit properties to ensure that images resize correctly without affecting website layout or quality across different devices.

Conclusion

All changes listed above were implemented to address the lecturer's Part 1 feedback and improve the professionalism, responsiveness, functionality, and presentation quality of the EcoCycle Solutions website.v
